Frequency of broad-spectrum beta-lactamase gene and evaluation of antimicrobial effect of *Teucrium polium* extract and essential oil in clinical isolates of *Klebsiella pneumonia*

Roghayeh Gholizadeh Doran Mahalleh, Farokh Rokhbakhsh Zamein, Javad Dahmardeh

**Abstract**

**Introduction:** β-Lactamase enzymes are one of the most important factors in generating antibiotic resistance among gram-negative bacteria. *Klebsiella pneumoniae* is an opportunistic pathogen from the *Enterobacteriaceae* family, which plays a major role in the development of hospital infections and people with underlying diseases.

**Objectives:** This study was aimed to investigate the antimicrobial effect of the essential oil of *Teucrium polium* on strains containing antibiotic resistant genes in clinical isolates of *Klebsiella pneumoniae* in Zahedan.

**Materials and Methods:** To identify chemical compounds and to investigate the antibacterial effects of *T. polium* extract, the leaves of this plant were collected from their natural habitat in May 2018 at full flowering stage. Extraction was carried out by water distillation method. Antibacterial activity of the extract of this plant and the least inhibitory concentration of growth on the resistant strains of *Klebsiella pneumoniae* was performed.

**Results:** The essential oil yield of *T. polium* was 75%. Of the 29 compounds identified in the essential oil of the *T. polium*, the combination of α-pinene with 12.52%, linalool was the highest in the essential oil of 10.63%. Of the 120 isolates of *K. pneumoniae*, 52 isolates in the initial screening were positive for ESBL production, of which 39 isolates (32.5%) were positive in the phenotypic confirmatory assay. Around 11 isolates (10.8%) had ampC genes. Based on the results of polymerase chain reaction (PCR), 76.9%, 12.8%, 30.8%, 28.2%, 25.7% and 56.4% of the isolates were carriers of FOX, EBC, ACC, DHA, CIT genes and MOX, respectively.

**Conclusion:** The results of antimicrobial resistance study of isolates showed that the highest resistance to erythromycin antibiotics (92.5%), cefotaxime (38.4%) and ceftiraxone (35.9%), respectively, while the highest susceptibility was observed in colistin antibiotics (98.3%), imipenem (90%) and amikacin (88.3%), respectively. The essential oil of the *T. polium* had a significant antibacterial effect. Due to the high percentage of high concentrations of α-pinene and linalool in the essential oil of the *T. polium*, in such a way that has antibacterial properties, *T. polium* can be used to cope with certain pathogenic bacteria.

**Key point**

The essential oil of the *Teucrium polium* had a noticeable antibacterial effect due to the high concentration of α-pinene and linalool.
The first clone was extracted, the slide was prepared and the sample was identified as K. pneumoniae by standard and differential microbiological methods. In the laboratory, the collected samples were confirmed and other required specifications were recorded. Then, the patient's name, hospitalization ward, sampling site, hospital of Zahedan, and the laboratory of the infectious disease research venter of Bu Ali hospital were recorded. All patient characteristics including age, gender, and hospitalization ward were recorded. The samples were inoculated on blood and MacConkey agar. Then catalase and oxidase tests were performed on single colonies (5). The following biochemical tests were performed for the final diagnosis of bacteria using the standard table: 1) antibacterial culture in a TSI agar, 2) bacterial culture of the bacteria in Simmons Citrate Agar, 3) culture of the bacteria in the SIM (Sulfide, Indole, Motility), 4) endodontic test using Kovacs, 5) culture of bacteria in MR-VP liquid, 6) culture of bacteria in urea agar, 7) culture of bacteria in lysine-decarboxylase, 8) culture of bacteria in ornithine decarboxylase, 9) culture of bacteria in arginine dihydrolase and 9) investigation of fermentation of sugars.

The leaves of the T. polium from their natural habitat were collected from the villages of Sistan and Baluchistan province in April of 2018, and after identification, they were dried at ambient temperature and then 150 g of crushed samples were extracted by water distillation using clevenger for three hours. Then, the extract was injected into a mass spectrometer (GC/MS) coupled with the mass spectrometry and corresponding chromatograms (3).

Objectives
The purpose of this study was to determine the antibiotic resistance pattern of K. pneumoniae strains isolated from clinical specimens of patients in educational hospitals of Zahedan, studying the frequency of AmpC β-lactamase genes in clinical isolates of K. pneumoniae, and comparing the therapeutic properties of T. polium with modern antibiotic therapy under laboratory conditions. Considering the creation of new gaps between conventional medicine and molecular medicine in the present age, antibiotic therapy can be selected by identifying the resistance gene in the bacteria in the shortest possible time based on the molecular analysis of the polymerase chain reaction (PCR). Introducing the results of this study will help the medical community to select the type and dose of medicine appropriately (4). If the results of infection suppression with T. polium to be positive, it can be helpful to identify and isolate the effective substance for introduction into the pharmaceutical industry.

Methods and Materials
This was a descriptive-analytical and laboratory study. K. pneumoniae samples were included urine, blood and respiratory tract secretions samples from April to September of 2018, around 230 samples of clinical isolates of K. pneumoniae from microbiology laboratories of Zahedan hospitals were gathered. After sample collection, suspected samples were transferred to the microbiology laboratory of the infectious disease research venter of Bu Ali hospital of Zahedan. All patient characteristics including the patient's name, hospitalization ward, sampling site, and other required specifications were recorded. Then in the laboratory, the collected samples were confirmed by standard and differential microbiological methods. Finally, 120 isolates were identified as K. pneumoniae.

The samples were inoculated on blood and MacConkey agar culture and incubated at 37°C. After 24 h incubation, the first clone was extracted, the slide was prepared and the germ staining was performed. The color of the colony was examined either on the face or on color on the MacConkey agar. Then catalase and oxidase tests were performed on single colonies (5). The following biochemical tests were performed for the final diagnosis of bacteria using the standard table; 1) antibacterial culture in a TSI agar, 2) bacterial culture of the bacteria in Simmons Citrate Agar, 3) culture of the bacteria in the SIM (Sulfide, Indole, Motility), 4) endodontic test using Kovacs, 5) culture of bacteria in MR-VP liquid, 6) culture of bacteria in urea agar, 7) culture of bacteria in lysine-decarboxylase, 8) culture of bacteria in ornithine decarboxylase, 9) culture of bacteria in arginine dihydrolase and 9) investigation of fermentation of sugars.

The leaves of the T. polium from their natural habitat were collected from the villages of Sistan and Baluchistan province in April of 2018, and after identification, they were dried at ambient temperature and then 150 g of crushed samples were extracted by water distillation using clevenger for three hours. Then, the extract was injected into a mass spectrometer (GC/MS) coupled with the mass spectrometry and corresponding chromatograms (3).

Antibiotic resistance and susceptibility patterns for 120 clinical isolates of K. pneumonia by disc diffusion method with antibiotic discs were as following; ceftriaxone (30 μg), ceftazidime (30 μg), cefotaxime (30 μg), ciprofloxacin (5 μg), gentamicin (10 μg), amikacin (30 μg), imipenem (10 μg), chloramphenicol (30 μg), colistin (10 μg) and erythromycin (15 μg) (prepared by MAST UK). In accordance with the Clinical Laboratory Standard Institute (CLSI) guidelines, the disk propagation method was used (6).

Disk diffusion
The microbial suspension prepared with dilution of interest was applied to the surface of the agar (next to the flame). Rotational rotations were done in the right and left directions to be uniformly distributed at the agar surface. After five minutes, the plates were placed in a slope and the microbial suspension was removed using the remaining sampler. Then, using sterile pins, the antibiotics were placed on the surface with proper spacing from each other and from the plate wall. Plates were placed at 37°C for 18 hours (7).

Result of disc diffusion
After 18 hours’ incubation at 37 °C, using a ruler under the light bulb, the diameter of the inhibition zone around the antibiotic discs was measured and evaluated using the CLSI instruction. The specimens were resistant, intermediate and sensitive. In each series, the standard strain of E. coli ATCC 25922 was used to control the quality of the discs (Figure 1) (8).
Antimicrobial effect of *Teucrium polium*

**Ethical issues**
The research followed the tenets of the Declaration of Helsinki. All study protocols were approved by the institutional ethical committee at Zahedan University (Ref #1099706040002). Also, they were in accordance with the guidelines of the National Health Institute (NIH1978) and Medical Research Council.

**Data analysis**
Data were analyzed using descriptive analyses as frequency and percentage. The results were reported as table and graph.

**Results**
Clinical samples were collected from different parts of the hospital including 75 isolates (62.5%) from outpatients, 23 isolates (19.2%) from intensive care unit (ICU), 8 isolates (6.7%) from emergency department, 6 isolates (5%) from infectious ward, 3 isolates (2.5%) from the internal section, 4 isolates (3.3%) from the women’s department and 1 isolate (0.8%) from the pediatric ward. Of the 120 samples of *K. pneumoniae*, 73 samples (60.8%) were related to the female population and 47 samples (39.2%) were related to the male population.

All strains of *K. pneumoniae* were analyzed after definitive isolation and diagnosis for disk diffusion test. The diameter of the inhibition zone around the discs was measured using a millimeter ruler and was evaluated in accordance with the CLSI 2017 standard table. The samples were resistant (R), intermediate (I) and sensitive (S) (Table 1) (6).

The results showed that the yield of *T. polium* collected from Sistan and Baluchistan province was 0.75%. Of the 28 compounds identified in the *T. polium* extract with 99.75%, α-pinene compounds with 12.52%, Linalool with 10.63%, and caryophyllene oxide with 9.69% have the highest percentage of extract. The extract of this plant on the gram-negative bacteria of *K. pneumoniae* has a diameter of 15 mm growth inhibitory effect. As shown in Figure 2, based on the results of PCR, in *Klebsiella pneumoniae* isolates 30 (76.9%), 5 (12.8%), 12 (30.8%), 11 (28.2%), 10 (25.7%), 22 (56.4%) of the isolates were carriers of FOX, EBC, ACC, DHA, CIT genes and MOX, respectively.

**Discussion**
Medicinal plants such as *T. polium* L. are one of the great important plants in the field of traditional medicine and modern medicine, with important pharmaceutical and nutritional compounds and antibacterial effects in botanical matters. (9). The results of *T. polium* analysis

![Figure 2. Frequency of genes producing broad-spectrum beta-lactamase enzymes in *Klebsiella pneumoniae* isolates.](image)
collected from Sistan and Baluchistan province showed that the extract yield of this species was 75%, which was less efficient than the study of Mohammad et al, that was carried out by steam distillation (3). The investigations showed that the total of 29 compounds identified in the \emph{T. polium} extract with 99.75%, α-pinene compounds with 12.52%, Linalool with 10.63%, and caryophyllene oxide with 9.69% had the highest percentage which had similarities and differences in comparison with other researchers.

In Iran and other parts of the world, a lot of research has been carried out on the different species of \emph{Teucrium}, including the identification of \emph{T. stocksianum} compounds by Jaimand et al that reported camphen (20.6%), α-cadinol (19.7%), myrcene (10.2%) and carvacrol (9.9%) as the main components of this herb (10). In another study, \emph{T. flavum} was shown to be the most active ingredient in α-caryophyllene (30.7%), germacrene (21.3%) α-humulene (8.8%) (9). \emph{T. orientale}. L. subsp \emph{orientale} has been reported with caryophyllene (33.5%), linalool (17.0%) and B-caryophyllene (9.3%) (11). In the study of \emph{T. persicum}, the compounds of caryophyllene oxide (10.6%), α-pinene (9.4%), linalool -α (7.8%), cadinene (7.4%), elemol (9 / 6%), α-cadinol (5.5%) had the highest levels (12). In the study on \emph{T. orientale}. L. subsp taylori of Lorestan province of Iran, linalool (28.66%), caryophyllene oxide (15.62%), 3-octanol (5.55%), B-pinene (8.75%) and B-caryophyllene (7.33%) were identified as the major combinations (13). In the study of the \emph{Teucrium} species in Italy, the \emph{T. fruticans} species had major components including β-pinene (21.0%), germacrene D (18.1%), β-myrcene (13.0%) and B-caryophyllene (12.0%) (14). In another study, the main component of \emph{T. polium} subsp. \emph{capitatum} were α-pinene (28.8%), β-pinene (7.2%) and p-cymene (0.07%) (15). Accordingly, in a study in Jordan, \emph{T. polium} showed the highest levels of 8-cedern-13-ol (24.8%), B-caryophyllene (7.8%), germacrene D (6.8%) and sabine (5.2%) (16, 17).

In this study, the combination of α-pinene with 12.52%, linalool with 10.63%, and caryophyllene oxide with 9.69% constitute the highest percentage of \emph{T. polium}, which are similar to other researchers in Iran and elsewhere in the world, which can be compared to the cause of the climatic and geographical conditions. The results of the study of antibacterial effects of \emph{T. polium} plant in Sistan and Baluchistan province showed that the plant’s antiseptic effect on gram-negative bacteria of \emph{K. pneumoniae} with a growth inhibitory diameter of 15 mm was. In a recent study, the antihypertensive effect of the \emph{T. polium} was experimentally approved (18). Furthermore a recent study detected that \emph{T. polium} significantly reduced cholesterol and triglyceride levels in experimental mice (19).

\emph{Klebsiella pneumoniae} is a gram-negative bacterium due to a range of diseases such as pneumonia, urinary tract infections, sepsisemia, soft tissue infections, bacterial meningitis and hepatitis. It is also the cause of hospital infections and acquired diseases. \emph{K. pneumoniae} in the hospital, where colonization is directly related to the length of hospitalization, dramatically increases. Long stay in a hospital increases the percentage of the presence of \emph{K. pneumoniae} on the skin of patients and even hospital staff (20).

In the present study, 120 isolates of \emph{K. pneumoniae} in hospitalized patients studied and the highest number was related to ICUs with 23 cases (19.2%). Previously, a study in Iran, on 200 clinical isolates of \emph{K. pneumoniae}, which were collected from the ICU, urology, respiratory and surgical departments during a year, showed the highest frequency was isolated from the ICU (21), which is consistent with our study.

Our results showed that the level of resistance to third-generation cephalosporin is relatively high among clinical isolates of \emph{K. pneumoniae} in Zahedan, since due to the lack of effective antibiotics for the treatment of these pathogens, this level of resistance can have many problems in the future. Finally, it should be noted that widespread control of ESBLs is difficult and may only be possible through the implementation of health and medical programs considering high cost. Therefore, the primary frequency control of the organisms producing ESBLs in a hospital or special department of the hospital is very important.

**Conclusion**

The results indicated the high inhibitory and microbial strength of \emph{T. polium}. The antibacterial effects of \emph{T. polium} can be attributed to the compounds of α-pinene and Linalool, which have been approved the antibacterial effects of these compounds. Therefore, due to the antibacterial effects of \emph{T. polium} extract in comparison with the third-generation cephalosporin antigens, this antibacterial agent can be used as a combination with antibacterial effects of natural origin. Our results showed that the level of resistance to third-generation cephalosporin among the clinical isolates of \emph{K. pneumoniae} in Zahedan was relatively high and due to the lack of effective antibiotics for the treatment of these pathogens, this resistance could be a major problem in the future in treatment of infections.
